1. (15 pts.) Solve (from scratch!) the boundary value problem
\[
\frac{\partial^2 u}{\partial x^2} + 6u = 3 \frac{\partial u}{\partial t}, \quad 0 < x < \pi, \quad t > 0,
\]
subject to
\[
u(0, t) = 0, \quad u(\pi, t) = 0, \quad t > 0,
\]
\[
u(x, 0) = \sin 3x, \quad 0 < x < \pi.
\]

\textbf{Ans.:} \(u(x, t) = e^{-t} \sin 3x\)

First we write
\[
u(x, t) = X(x)T(t).
\]
Plug this into the pde, to get
\[
X''(x)T(t) + 6X(x)T(t) = 3X(x)T'(t).
\]
Divide by \(X(x)T(t)\):
\[
\frac{X''(x)}{X(x)} + 6 = 3 \frac{T'(t)}{T(t)}.
\]
It is convenient to move the 6 to the right, getting:
\[
\frac{X''(x)}{X(x)} = 3 \frac{T'(t)}{T(t)} - 6.
\]
The left side does not depend on \(t\) and the right side does not depend on \(x\). Since they are equal to each other neither of them depends on \(x\) or \(t\), in other words, they are equal to the same constant. There are three cases, the constant is positive, zero, or negative. But if that constant is positive, there is no way that we get \(u(x, 0)\) being a trig. function, so we can assume that the constant is negative, and we write it as \(-\lambda^2\). So we have two odes:
\[
\frac{X''(x)}{X(x)} = -\lambda^2.
\]
\[
3 \frac{T'(t)}{T(t)} - 6 = -\lambda^2.
\]
Cleaning up:

\[ X''(x) + \lambda^2 X(x) = 0 \]
\[ T'(t) - (2 - \lambda^2/3)T(t) = 0 \]

The general solution of the first equation is \( c_1 \cos \lambda x + c_2 \sin \lambda x \). The general solution of the second one is \( c_3 e^{(2 - \lambda^2/3)t} \). So product solutions are \( u(x, t) = (\cos \lambda x)(e^{(2 - \lambda^2/3)t}) \) and \( u(x, t) = (\sin \lambda x)e^{(-2 + \lambda^2/3)t} \). Since \( u(0, t) = 0 \) the first family is no good. So we are left with \( u(x, t) = \sin \lambda x e^{(2 - \lambda^2/3)t} \). Using \( u(\pi, t) = 0 \) gives \( \sin(\lambda \pi) = 0 \). Solving this trig. equation for \( \lambda \) gives \( \lambda \pi = n\pi \) so \( \lambda = n \) (\( n \) integer).

So far the candidates for building blocks are \( u(x, t) = \sin(nx) e^{(2 - n^2/3)t} \). By the principle of superposition any (finite or infinite) linear combination of them is a solution.

\[ u(x, t) = \sum_{n=1}^{\infty} A_n \sin(nx) e^{(2 - n^2/3)t} \]

So \( u(x, 0) \) gives a Fourier Sine expansion. In general given the initial function \( u(x, 0) \) we would find its Fourier Sine expansion and then stick \( e^{(2 - n^2/3)t} \) after the \( \sin nx \) in the sigma. But this is a lucky case. \( u(x, 0) \) is a pure sine function, whose Fourier-Sine expansion equal itself! So \( n = 3 \) is the only term and we stick \( e^{(2 - 3^2/3)t} = e^{-t} \) after the \( \sin 3x \), getting that the answer is \( (\sin 3x)e^{-t} \).
2. (15 pts.) Find the eigenvalues $\lambda_n$, and the corresponding eigenfunctions $y_n(x)$ for the following boundary value problem.

$$ y'' + \lambda^2 y = 0 \quad , \quad y'(0) = 0 \quad , \quad y'(10) = 0 \ . $$

\[ \text{Ans.:} \quad \lambda_n = \frac{n\pi}{10} \quad \quad y_n(x) = \cos\left(\frac{n\pi}{10}x\right) \]

The general solution of the ode is

$$ y(x) = c_1 \cos \lambda x + c_2 \sin \lambda x \ . $$

In order to take care of the boundary conditions, we need to first find $y'(x)$:

$$ y'(x) = -\lambda c_1 \sin \lambda x + \lambda c_2 \cos \lambda x \ . $$

So $y'(0) = \lambda c_2$. Since means that $c_2 = 0$ and $y(x)$ must be of the form

$$ y(x) = c_1 \cos \lambda x $$

and

$$ y'(x) = -c_1 \lambda \sin \lambda x $$

Since $y'(10) = 0$ we need

$$ y'(10) = -c_1 \lambda (\sin \lambda 10) \ . $$

$c_1$ better not be zero, so we need to solve the trig. eq. $\sin(\lambda 10) = 0$. But the solution of $\sin w = 0$ is $w = n\pi$ ($n$ integer), so we have $\lambda 10 = n\pi$. Solving for $\lambda$ we get that the eigenvalues are $\lambda_n = \frac{n\pi}{10}$. Going back to $y(x)$ (NOT $y'(x)$), we have (we can set $c_1 = 1$)

$$ y_n(x) = \cos\left(\frac{n\pi}{10}x\right) \ . $$
3. (15 pts.) Solve the pde

\[ 25u_{xx} = u_{tt}, \quad 0 < x < \pi, \quad t > 0, \]

subject to the boundary-conditions

\[ u(0, t) = 0, \quad u(\pi, t) = 0, \quad t > 0, \]

and the initial conditions

\[ u(x, 0) = \sin 4x, \quad u_t(x, 0) = 5\sin x + 10\sin 5x, \quad 0 < x < \pi. \]

**Ans.:**

\[ u(x, t) = \sin 4x \cos 20t + \sin x \sin 5t + \frac{2}{5} \sin 5x \sin 25t. \]

This is the wave equation with \( a = 5 \), with the usual (string-instrument in music) boundary conditions. Since both \( u(x, 0) \) and \( u_t(x, 0) \) are either pure sine wave functions or finite combinations we can safely use Dr. Z.'s shortcut method. To get \( u(x, t) \) from \( u(x, 0) \) and \( u_t(x, 0) \), we multiply each \( \sin nx \) term in \( u(x, 0) \) by \( \cos (nat) \), and we multiply each \( \sin nx \) term in \( u_t(x, 0) \) by \( \frac{\sin (nat)}{na} \), and add them all up. So

\[ u(x, t) = (\sin 4x) \cos (5 \cdot 4t) + 5(\sin x) \frac{\cos (5t)}{5} + 10(\sin 5x) \frac{\sin (5 \cdot 5t)}{5 \cdot 5} = \sin 4x \cos 20t + \sin x \sin 5t + \frac{2}{5} \sin 5x \sin 25t. \]
4. (15 pts.) Find the half-range cosine expansion of \( f(x) = x \) on \((0, 2\pi)\).

\[
\text{Ans.:} \quad \pi - 8 \sum_{k=0}^{\infty} \frac{1}{(2k+1)^2} \cos\left(\frac{2k+1}{2} x\right).
\]

Recall that the first step is to move from the interval \((0, L)\) to the interval \((0, \pi)\) by defining 
\( g(x) = f\left(\frac{x}{L}\right) \). Here \( L = 2\pi \) so
\[
g(x) = f\left(\frac{2\pi}{\pi}\right) = f(2x) = 2x,
\]
on \((0, \pi)\). Recall that at the very end, once we would have the half-range cosine expansion of \( g(x) \), we would go back to \( f(x) \) using \( f(x) = g(x/2) \).

Using the formula sheet
\[
a_0 = \frac{2}{\pi} \int_0^{\pi} g(x) \, dx = \frac{2}{\pi} \int_0^{\pi} (2x) \, dx = \frac{2}{\pi} x^2 \bigg|_0^\pi = \frac{2}{\pi} (\pi^2 - 0^2) = 2\pi.
\]

Next, 
\[
a_n = \frac{2}{\pi} \int_0^{\pi} 2x \cos nx \, dx = \frac{4}{\pi} \int_0^{\pi} x \cos nx \, dx.
\]

From the formula sheet:
\[
\int x \cos nx \, dx = \frac{\cos nx + nx \sin nx}{n^2} + C.
\]

So
\[
a_n = \frac{4}{\pi} \int_0^{\pi} x \cos nx \, dx = \frac{4}{\pi} \frac{\cos nx + nx \sin nx}{n^2} \bigg|_0^\pi = \frac{4}{\pi} \left(\frac{\cos n\pi + n\pi \sin n\pi}{n^2} - \frac{\cos(0) + n\pi \sin(0)}{n^2}\right).
\]

Since \( \sin n\pi = 0, \sin 0 = 0, \cos 0 = 1 \) and \( \cos n\pi = (-1)^n \) (since \( n \) is an integer) this becomes:
\[
a_n = \frac{4}{\pi} \frac{(-1)^n - 1}{n^2}.
\]

From the formula sheet, the half-range cosine expansion of \( g(x) \) (over \((0, \pi)\)) is:
\[
g(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos nx,
\]
so

\[ g(x) = \pi + \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^n - 1}{n^2} \cos nx. \]

To get back to \( f(x) \), we use \( f(x) = g(x/2) \) getting

\[ f(x) = \pi + \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^n - 1}{n^2} \cos \left( \frac{nx}{2} \right). \]

This is a **correct answer** that would give you 14 points. To get the remaining point, you would realize that when \( n \) is even \((-1)^n - 1 \) is 0 and when \( n \) is odd it is always \(-2\). So writing \( n = 2k + 1 \) \((k = 0, 1, \ldots)\), we get a better answer

\[ f(x) = \pi - \frac{8}{\pi} \sum_{k=0}^{\infty} \frac{1}{(2k+1)^2} \cos \left( \frac{(2k+1)x}{2} \right). \]
5. (15 pts. altogether)

(a) (8 points) Show that the following set of two functions, over the given interval and weight function, is an orthogonal set.

\[ \{ f_1(x) = 1, \quad f_2(x) = 5x - 3 \} \quad [0, 1] \quad w(x) = \sqrt{x} \]

(b) (7 points) Using orthogonality (no credit for other methods!) find numbers \( c_1, c_2 \) such that

\[ 5x = c_1 f_1(x) + c_2 f_2(x) \]

Ans. to b): \( c_1 = 3 \quad c_2 = 1 \)

(a)

\[
(f_1(x), f_2(x))_{w(x)} = \int_0^1 (1)(5x-3)\sqrt{x} \, dx = \int_0^1 (5x^{3/2} - 3x^{1/2}) \, dx = 5 \frac{x^{5/2}}{5/2} \Bigg|_0^1 - 3 \frac{x^{3/2}}{3/2} \Bigg|_0^1 = (2x^{5/2} - 2x^{3/2}) \Bigg|_0^1 = 2 - 2 = 0
\]

So they are orthogonal with respect to \( w(x) = \sqrt{x} \) over the interval \([0, 1]\).

(b)

\[
c_1 = \frac{(f_1(x), f_1(x))_{w(x)}}{(f_1(x), f_1(x))_{w(x)}} = \frac{\int_0^1 (1)(5x)\sqrt{x} \, dx}{\int_0^1 (1)(1)\sqrt{x} \, dx} = \frac{\int_0^1 5x^{3/2} \, dx}{\int_0^1 x^{1/2} \, dx} = \frac{2x^{5/2}}{(2/3)x^{3/2}} \Bigg|_0^1 = \frac{(2 - 0)}{(2/3)(1 - 0)} = 3
\]

Now \( c_2 \) can be computed similarly, but it is rather tedious. By this stage, once we computed \( c_1 \) using orthogonality, it is OK to “cheat” and use simple algebra. Since

\[ 5x = (3)(1) + c_2(5x - 3) \]

it is obvious that \( c_2 = 1 \) and it would have been foolish to do it the long way.
6. (15 pts.) Solve:

\[ u_{xx} + u_{yy} = 0 , \quad 0 < x < \pi , \quad 0 < y < 1 , \]

Subject to

\[ u(0, y) = 0 , \quad u(\pi, y) = 0 , \quad 0 < y < 1 ; \]
\[ u(x, 0) = 0 , \quad u(x, 1) = (\sinh 4) \sin 4 x + (\sinh 7) \sin 7 x + (\sinh 10) \sin 10 x , \quad 0 < x < \pi . \]

**Ans.:** \( u(x, y) = \sin 4x \sinh 4y + \sin 7x \sinh 7y + \sin 10x \sinh 10y \)

There are eight kinds of product solutions to Laplace’s equation:

\[
\begin{align*}
    u(x, y) &= \sin \lambda x \sinh \lambda y , \\
    u(x, y) &= \sin \lambda x \cosh \lambda y , \\
    u(x, y) &= \cos \lambda x \sinh \lambda y , \\
    u(x, y) &= \cos \lambda x \cosh \lambda y , \\
\end{align*}
\]

and the other ones obtained by transposing \( x \) and \( y \). Since \( u(0, y) = 0 \) and \( u(x, 0) \) none of them survives except for \( \sin \lambda x \sinh \lambda y \). Since \( u(\pi, y) = 0 \) we must have \( \sin \lambda \pi = 0 \) so \( \lambda \pi = n\pi \) (\( n \) integer) so \( \lambda = n \) (integer). So the building blocks for the pde plus the boundary conditions and the initial condition \( u(x, 0) = 0 \) are

\[ \sin nx \sinh ny . \]

By the principle of superposition, any **linear combination** (finite or infinite)

\[ u(x, y) = A_1 \sin x \sinh y + A_2 \sin 2x \sinh 2y + \ldots + A_n \sin nx \sinh n + \ldots \]

is yet another solution. Plugging-in \( y = 1 \) gives

\[ u(x, 1) = A_1 \sin x(\sinh 1) + A_2 \sin 2x(\sinh 2) + \ldots + A_n \sin nx(\sinh n) + \ldots \]

So we need to find the half-range sine series of \( u(x, 1) \) get the coefficients \( A_1, A_2, \ldots \) and go back to \( u(x, y) \). In this problem \( u(x, 1) \) is already a finite combination of pure sine waves (three of them) so it is already a sine-series. The \( n \) that show up are \( n = 4, n = 7 \) and \( n = 10 \), so it obvious that

\[ u(x, 1) = \sin 4x \sinh 4y + \sin 7x \sinh 7y + \sin 10x \sinh 10y \]
7. (15 pts.) Find product solutions, if possible, to the partial differential equation

\[ 2 \frac{\partial u}{\partial x} + 3 \frac{\partial u}{\partial y} = 0. \]

**Ans.:** \( u(x, y) = Ce^{\frac{k}{2}x}e^{-\frac{k}{3}y} \) or \( u(x, y) = Ce^{k(3x-2y)} \)

Let \( u(x, y) = X(x)Y(y) \).

Plug into the ode

\[ 2X'(x)Y(y) + 3X(x)Y'(y) = 0. \]

Divide by \( X(x)Y(y) \):

\[ \frac{2X'(x)Y(y) + 3X(x)Y'(y)}{X(x)Y(y)} = 0. \]

Simplify

\[ \frac{2 \cdot X'(x)}{X(x)} + 3 \cdot \frac{Y'(y)}{Y(y)} = 0. \]

Leave the \( X(x) \) stuff on the left and move the \( Y(y) \) to the right:

\[ 2 \cdot \frac{X'(x)}{X(x)} = -3 \cdot \frac{Y'(y)}{Y(y)}. \]

The left side does not depend on \( y \), the right side does not depend on \( x \). They are equal to each other, so neither depend on \( x \) or \( y \), so they are both equal to the same constant, let’s call it \( k \). We have two odes:

\[ \frac{2 \cdot X'(x)}{X(x)} = k, \quad \frac{-3 \cdot Y'(y)}{Y(y)} = k. \]

Cleaning up

\[ X'(x) - \frac{k}{2}X(x) = 0, \]

\[ Y'(y) + \frac{k}{3}Y(y) = 0. \]

The general solutions are \( X(x) = c_1e^{\frac{k}{2}x}, Y(y) = c_2e^{-\frac{k}{3}y} \), so \( u(x, y) = c_1c_2e^{\frac{k}{2}x}e^{-\frac{k}{3}y} \).

Putting \( C = c_1c_2 \) we get the answer \( u(x, y) = Ce^{\frac{k}{2}x}e^{-\frac{k}{3}y} \). Replacing \( k \) by \( 6k \) and doing the algebra gives the nicer forms.
8. (15 pts.) Find 
\[ L^{-1} \left\{ \frac{3s^2 - 1}{s^3 - s} \right\} \]

\textbf{Ans.:} 
\[ 1 + e^{-t} + e^t \]

We first factorize the denominator
\[ \frac{3s^2 - 1}{s(s - 1)(s + 1)} \]

We next try \textbf{partial fraction decomposition} using the template
\[ \frac{3s^2 - 1}{s(s - 1)(s + 1)} = \frac{A}{s} + \frac{B}{s - 1} + \frac{C}{s + 1} \]

Next we take common denominator of the right
\[ \frac{3s^2 - 1}{s(s - 1)(s + 1)} = \frac{A(s + 1)(s - 1) + Bs(s - 1) + Cs(s + 1)}{s(s - 1)(s + 1)} \]

The bottoms automatically match, so we equate the tops
\[ 3s^2 - 1 = A(s + 1)(s - 1) + Bs(s - 1) + Cs(s + 1) \]

Convenient values: \( s = 0 \) gives \(-1 = A(1)(-1) \) so \( A = 1; \) \( s = 1 \) gives \( 2 = C(1)(2) \) so \( C = 1; \) \( s = -1 \) gives \( 2 = B(-1)(-2) \) so \( B = 1. \) Going back to the template, we have:
\[ \frac{3s^2 - 1}{s(s - 1)(s + 1)} = \frac{1}{s} + \frac{1}{s - 1} + \frac{1}{s + 1} \]

Now, and only now, do we apply \( L^{-1}: \)
\[ L^{-1}\left\{ \frac{3s^2 - 1}{s(s - 1)(s + 1)} \right\} = L^{-1}\left\{ \frac{1}{s} \right\} + L^{-1}\left\{ \frac{1}{s - 1} \right\} + L^{-1}\left\{ \frac{1}{s + 1} \right\} \]

And the answer follows from the table: \( L^{-1}\left\{ \frac{1}{s} \right\} = 1 \) and \( L^{-1}\left\{ \frac{1}{s-1} \right\} = e^{at} \)
9. (15 pts.) 9a. (7 points) Compute $\mathcal{L}\{(t + 6)\mathcal{U}(t - 6)\}$.

Ans.:

$$\frac{e^{-6s}}{s^2} + 12 \frac{e^{-6s}}{s}.$$

We first write (so that we can use the formula sheet formula $\mathcal{L}\{f(t-a)\mathcal{U}(t-a)\} = F(s)e^{-as}$)

$$\mathcal{L}\{(t + 6)\mathcal{U}(t - 6)\} = \mathcal{L}\{((t - 6) + 12)\mathcal{U}(t - 6)\} = \mathcal{L}\{(t - 6)\mathcal{U}(t - 6)\} + 12\mathcal{L}\{\mathcal{U}(t - 6)\}.$$

Using the formula with $f(t) = t$ and $f(t) = 1$ for the first and second term gives the answer.

9b. (8 points) Compute

$$\mathcal{L}^{-1}\left\{\frac{e^{-4s}}{(s + 2)^3}\right\}.$$

Ans.:

$$\frac{1}{2}(t - 4)^2 e^{-2(t-4)}\mathcal{U}(t - 4).$$

Here $F(s) = \frac{1}{(s+2)^3}$, $a = 4$ in the formula $\mathcal{L}^{-1}\{F(s)e^{-as}\} = f(t-a)\mathcal{U}(t-a)$. From the table $f(t) = \mathcal{L}^{-1}\left\{\frac{1}{(s+2)^3}\right\} = \frac{1}{2}t^2 e^{-2t}$. 

10. (15 pts.) Evaluate

\[ \mathcal{L}\{ \int_{0}^{t} \tau^{15} e^{3\tau} \, d\tau \} \, . \]

**Ans.:**

\[ \frac{15!}{s^{16}(s-3)} \, . \]

The integral is the convolution \( t^{15} e^{3t} \). Using the formula \( \mathcal{L}\{ f(t) * g(t) \} = \mathcal{L}\{ f(t) \} \mathcal{L}\{ g(t) \} \), we have

\[ \mathcal{L}\{ t^{15} e^{3t} \} = \mathcal{L}\{ t^{15} \} \mathcal{L}\{ e^{3t} \} = \frac{15!}{s^{16}} \cdot \frac{1}{s-3} = \frac{15!}{s^{16}(s-3)} \, . \]
11. (15 pts.) Solve the initial-value problem

\[ y'' + 10y' + 25y = \delta(t-2) , \quad y(0) = 0 , \quad y'(0) = 0 . \]

**Ans.:** \((t-2)e^{-5(t-2)}U(t-2)\)

We apply \(\mathcal{L}\) to the ode, getting

\[ \mathcal{L}\{y'' + 10y' + 25y\} = \mathcal{L}\{\delta(t-2)\} \]

Putting, as usual \(\mathcal{L}\{y(t)\} = Y(s)\),

\[ s^2Y(s) - sy(0) - y'(0) + 10(sY(s) - y(0)) + 25Y(s) = e^{-2s} . \]

Since \(y(0) = 0, y'(0) = 0\), this becomes

\[ s^2Y(s) + 10sY(s) + 25Y(s) = e^{-2s} . \]

Factoring:

\[ (s^2 + 10s + 25)Y(s) = e^{-2s} . \]

Solving for \(Y(s)\):

\[ Y(s) = \frac{e^{-s}}{s^2 + 10s + 25} = \frac{e^{-2s}}{(s + 5)^2} . \]

So

\[ y(t) = \mathcal{L}^{-1}\{Y(s)\} = \mathcal{L}^{-1}\left\{ \frac{e^{-2s}}{(s + 5)^2} \right\} . \]

We use the formula \(\mathcal{L}^{-1}\{e^{-as}F(s)\} = f(t-a)U(t-a)\). Here \(a = 1\) and \(f(t) = \mathcal{L}^{-1}\left\{ \frac{1}{(s+5)^2} \right\} = te^{-5t}\) (from the table), so we get the answer.
12. (15 pts.) Solve the pde
\[ u_{xx} + 12 \sin 4x \sin 2t = u_{tt}, \quad 0 < x < \pi, \quad t > 0, \]
subject to the **boundary-conditions**

\[ u(0, t) = 0, \quad u(\pi, t) = 0, \quad t > 0, \]

and the **initial conditions**

\[ u(x, 0) = 0, \quad u_t(x, 0) = 0, \quad 0 < x < \pi. \]

**Ans.:**

\[ u(x, t) = (\sin 2t - \frac{1}{2} \sin 4t) \sin 4x. \]

**Sketch of solution:** Let \( U(x, s) = \mathcal{L}\{u(x, t)\} \) and call it \( U(x) \) for short. We get the ode

\[ U''(x) - s^2 U(x) = \sin(4x) \frac{-24}{s^2 + 4}. \]

The general solution of the homog. version is \( c_1 e^{sx} + c_2 e^{-sx}. \) A template for a particular solution is \( A \sin 4x \) (note since \( U'(x) \) does not show up we don’t need to take \( A \cos 4x \) since \( B \) is destined to be 0). This yields \( A = \frac{24}{(s^2 + 4)(s^2 + 16)}, \) so a particular solution is

\[ U(x) = \frac{24}{(s^2 + 4)(s^2 + 16)} \sin 4x, \]

and the general solution of the ode is

\[ U(x) = c_1 e^{sx} + c_2 e^{-sx} + \frac{24}{(s^2 + 4)(s^2 + 16)} \sin 4x. \]

By using the boundary conditions \( U(0) = 0, U(\pi) = 0 \) we get that \( c_1 = 0 \) and \( c_2 = 0, \) so

\[ U(x) = \frac{24}{(s^2 + 4)(s^2 + 16)} \sin 4x. \]

Finally

\[ u(x, t) = \mathcal{L}^{-1}\left\{ \frac{24}{(s^2 + 4)(s^2 + 16)} \sin 4x \right\} = \sin 4x \mathcal{L}^{-1}\left\{ \frac{24}{(s^2 + 4)(s^2 + 16)} \right\}. \]

By partial fractions (short cut: consider mentally \( s^2 \) as the variable)

\[ \frac{24}{(s^2 + 4)(s^2 + 16)} = \frac{2}{s^2 + 4} - \frac{2}{s^2 + 16}. \]

So

\[ u(x, t) = \sin 4x \left( \sin 2t - \frac{1}{2} \sin 4t \right). \]
13. (10 pts.)
Find the Fourier integral representation of

\[ f(x) = \begin{cases} 
  e^{2x}, & \text{if } x < 0; \\
  e^{-3x}, & \text{if } x \geq 0; 
\end{cases} \]

Ans.:

\[
\frac{1}{\pi} \int_{0}^{\infty} \left( \frac{2}{\alpha^2 + 4} + \frac{3}{\alpha^2 + 9} \right) \cos(\alpha x) \, d\alpha + \frac{1}{\pi} \int_{0}^{\infty} \left( -\frac{\alpha}{\alpha^2 + 4} + \frac{\alpha}{\alpha^2 + 9} \right) \sin(\alpha x) \, d\alpha
\]

Sketch of solution: use the formulas for \( A(\alpha) \) and \( B(\alpha) \) from the cheatsheet, and then use the formulas for \( \int e^{ax} \cos bx \, dx \) and \( \int e^{ax} \sin bx \, dx \) to evaluate the improper integrals, remembering that \( \frac{\sin x}{x} \) tends to zero as \( x \to \infty \) hence ‘informally’, while \( \cos(-\infty) \) and \( \sin(-\infty) \) are utter nonsense, \( e^{-\infty} \cos(-\infty) \) and \( e^{-\infty} \sin(-\infty) \) both equal 0.
14. (10 pts.) Find all the eigenvalues of the matrix
\[
\begin{bmatrix}
10 & -6 \\
12 & -7
\end{bmatrix},
\]
and determine a basis for each eigenspace.

**Ans.** smaller eigenvalue: 1 corresponding eigenfunction: \[
\begin{bmatrix}
2 \\
3
\end{bmatrix}.
\]
larger eigenvalue: 2 corresponding eigenfunction: \[
\begin{bmatrix}
3 \\
4
\end{bmatrix}.
\]

\[
\begin{align*}
\det \begin{bmatrix} 10 - \lambda & 12 \\ 4 & -7 - \lambda \end{bmatrix} &= (10-\lambda)(-7-\lambda)-(6)(12) = (\lambda+7)(\lambda-10)+72 = \lambda^2-3\lambda+2 = (\lambda-1)(\lambda-2) \\
\text{So the characteristic equation is} \\
(\lambda - 1)(\lambda - 2) &= 0 .
\end{align*}
\]
Solving it: gives \(\lambda = 1\) and \(\lambda = 2\) as the two eigenvalues. For each of these we need to find the corresponding eigenvectors. When \(\lambda = 1\) we have to find a vector \[
\begin{bmatrix}
a \\
b
\end{bmatrix}
\]
such
\[
\begin{bmatrix}
10 & -6 \\
12 & -7
\end{bmatrix} \begin{bmatrix}
a \\
b
\end{bmatrix} = \begin{bmatrix}
a \\
b
\end{bmatrix} .
\]
Doing the matrix-multiplication, we get two equations
\[
10a - 6b = a, \quad 12a - 7b = b .
\]
Cleaning-up
\[
9a - 6b = 0, \quad 12a - 8b = 0 .
\]
But the second is a multiple of the first, so we can discard it, and get that the general solution is \(b = 9a/6 = 3a/2\). Plugging this into the template \[
\begin{bmatrix}
a \\
3/2a
\end{bmatrix}
\]
Taking \(a = 2\) (we can take any non-zero value for \(a\)) gives the eigenvector for \(\lambda = 1\). \[
\begin{bmatrix}
2 \\
3
\end{bmatrix}.
\]
When $\lambda = 2$ we have to find a vector $\begin{bmatrix} a \\ b \end{bmatrix}$ such that

$$\begin{bmatrix} 10 & -6 \\ 12 & -7 \end{bmatrix} \begin{bmatrix} a \\ b \end{bmatrix} = 2 \begin{bmatrix} a \\ b \end{bmatrix}.$$  

Doing the matrix-multiplication, we get two equations

$$10a - 6b = 2a, \quad 12a - 7b = 2b.$$

Cleaning-up

$$8a - 6b = 0, \quad 10a - 8b = 0.$$

But the second is a multiple of the first, so we can discard it, and get that the general solution is $b = 8a/6 = 4a/3$. Plugging this into the template $\begin{bmatrix} a \\ 4a/3 \end{bmatrix}$ taking $a = 3$ (we can take any non-zero value for $a$) gives the eigenvector for $\lambda = 2$.  

$$\begin{bmatrix} 3 \\ 4 \end{bmatrix}.$$
